

Azure Application and Network Cost Optimization Guide

This fictional guide covers App Service, container registries, public IP addresses, and supporting governance. It is designed to return practical suggestions when those resource types are queried.

App Service Plans

An App Service Plan is billed for allocated workers, not merely traffic. Applications sharing the same plan also share its scaling behavior and capacity constraints.

- Review worker utilization, peak traffic, and autoscale rules before lowering a Premium plan SKU or worker count.
- Separate workloads with conflicting scaling patterns only when the operational value exceeds the extra plan cost.
- Use deployment slots and always-on features only where they are necessary for availability or deployment safety.
- Test any SKU change during a controlled window and confirm application performance after the change.

Network and container registry cleanup

Public IP addresses, load balancers, NAT gateways, and premium registries can create recurring spend even at low utilization.

- Review public IP addresses with no assigned IP or no active dependency; remove them after change approval.
- Choose the container registry SKU from replication, private endpoint, and retention needs; Premium is not required for every workload.
- Apply image retention policies to remove untagged and obsolete container images.
- Use budgets, anomaly alerts, and owner tags so new spend is visible quickly.

Dummy scenario

democost-app-plan is a PremiumV3 plan with three workers. Validate measured demand and autoscaling before downsizing. democost-unused-ip has no allocated address and should be reviewed for removal. democostregistry is Premium and should be checked against its feature requirements.
